SWMU	solid-waste management unit
TCE	trichloroethene
TCOPC	total contaminants of potential concern
VC	vinyl chloride
VOCs	volatile organic compounds
WWNA	Wastewater Neutralization Area

1.0 Introduction

The Young - Rainey Science, Technology, and Research Center (STAR Center) is a former U.S. Department of Energy (DOE) facility constructed in the mid-1950s in Pinellas County, Florida. The 99-acre STAR Center is located in Largo, Florida, and lies in the northeast quarter of Section 13, Township 30 South, Range 15 East (Figure 1). While it was owned by DOE, the facility primarily manufactured neutron generators for nuclear weapons. Other products manufactured at the STAR Center have included radioisotopically powered thermoelectric generators, thermal batteries, specialty capacitors, crystal resonators, neutron detectors, lightning-arrestor connectors, and vacuum-switch tubes. In 1987, the U.S. Environmental Protection Agency (EPA) performed a Resource Conservation and Recovery Act (RCRA) Facility Assessment (RFA) (EPA 1988) at the site to gather information on potential releases of hazardous materials. In February of 1990, EPA issued a Hazardous and Solid Waste Amendments (HSWA) permit to DOE, enabling DOE to investigate and perform remediation activities in those areas designated as solid-waste management units (SWMUs), contaminated by hazardous materials resulting from DOE operations. On March 17, 1995, DOE sold the facility to the Pinellas County Industrial Council (PCIC). The sales contract included clauses to ensure continued compliance with federal, state, and local regulations while DOE remediates the site. On July 1, 1999, the PCIC was disestablished, and ownership of the STAR Center changed to the Pinellas County government. In November 2000, the State of Florida received HSWA authorization from EPA. The Florida Department of Environmental Protection (FDEP) issued a new HSWA permit to DOE in January 2002.

The administration of DOE activities at the facility is the responsibility of the DOE Office of Legacy Management in Grand Junction, Colorado. S.M. Stoller Corporation (Stoller), a prime contractor to DOE's Office of Legacy Management, provides technical support to DOE for remediation and closure of all active SWMUs on site.

The EPA RFA Report and the HSWA permit identified 15 sites at the former DOE facility that may have experienced environmental contamination as a result of past activities. Upon completion of the RCRA Facility Investigation (DOE 1991), 11 of the 15 SWMUs were recommended by DOE and approved by EPA Region IV and FDEP for no further action (DOE 1994b). A twelfth site, the Former Pistol Range Site, was remediated in 1993; it was recommended by DOE, and approved by EPA Region IV and FDEP, for no further action.

Two additional SWMUs, the West Fenceline Site and the Wastewater Neutralization Area/ Building 200 (WWNA/Building 200), were identified after the HSWA permit was issued, bringing the total to 17 SWMUs that have been identified and investigated at the STAR Center. The remediation of the West Fenceline Site was completed in 1997, and DOE recommended—and EPA Region IV and FDEP approved—no further action, for a total of 13 SWMUs remediated. A Corrective Measures Study (CMS)/Corrective Measures Implementation Plan (CMIP) was prepared and submitted in 1997 to EPA Region IV and FDEP to address the contamination at the WWNA/Building 200 Area.

Therefore, there are currently four SWMUs that have contamination in the surficial aquifer groundwater at levels in excess of protective standards. These four SWMUs are the Old Drum Storage Site (PIN06), the Industrial Drain Leaks-Building 100 Area (PIN12), the Northeast Site

(PIN15), and the WWNA/Building 200 Area (PIN18). Two SWMUs, PIN06 and PIN12, are collectively known as the Building 100 Area. Figure 2 depicts the location of the four SWMUs. Additional background information relative to each SWMU is briefly described below.

This document also serves as the semiannual progress report for each of these four SWMUs. The results of monitoring activities and a summary of ongoing and projected work are provided in this report.

1.1 Building 100 Area

The Building 100 Area (PIN06 and PIN12) is located in the southeast portion of the STAR Center. The Old Drum Storage Site is the former location of a concrete storage pad equipped with a drain and containment system used to store hazardous waste including methylene chloride, ignitable liquids, arsenic, and calcium chromate solids (DOE 1987a). Empty drums containing residual waste solvents were also stored in this area (DOE 1987b). The concrete pad was located near the northwest corner of Building 100. The pad was removed in October 1983 in accordance with an FDEP closure permit (DOE 1987a), and a closure report was submitted to FDEP in August 1986 (DOE 1986). The decommissioning of the pad and the cessation of drum storage effectively removed the potential for a future contaminant source at PIN06.

Building 100 is the largest building at the STAR Center and covers approximately 11 acres. In the past, offices, laboratories, and production facilities for DOE were housed in the building. SWMU PIN12 consists of the liquid waste drainage system that formerly served Building 100. Four individual drainage systems (sanitary, chemical, health physics, and storm water) were present within the building. In 1989, all four drainage systems were investigated, including verifying the system routing and the condition of underground and aboveground piping and ancillary equipment (EMC 1989). As a result of this investigation, the health physics and chemical drainage systems were flushed, grouted, and abandoned (DOE 1997). Some of the chemical drain lines were replaced by an aboveground system currently used by tenants of the building.

A CMS and CMIP were completed and approved for the Building 100 Area because volatile organic compounds (VOCs) concentrations measured in groundwater at the Old Drum Storage Site (PIN06) and one monitoring well located at the northwest corner of Building 100 (PIN12) exceeded the Safe Drinking Water Act and FDEP maximum contaminant levels (MCLs). Subsequent investigations revealed elevated VOCs concentrations under Building 100 and downgradient to the southeast as well. On August 15, 2000, EPA approved the Building 100 CMIP Addendum; FDEP approved the document on November 15, 1999.

In May 2001, DOE began an analysis of the potential remediation strategies for the three Building 100 Area tasks: plume control, source treatment, and dissolved phase treatment. The *Building 100 Area Remediation Technology Screening Report* (DOE 2001) assembled a list of remediation technologies, categorized them into the remediation tasks, and conducted an initial screening of the technologies. This initial screening eliminated the technologies that obviously would not work and recommended technologies that should be retained for detailed evaluation at a later time.

The *Building 100 Area Plume Control Technology Selection Report*, prepared in February 2002, conducted a detailed evaluation of five plume control technologies and recommended that enhanced bioremediation should be implemented for plume control at the Building 100 Area.

In-situ enhanced bioremediation to control the plume of dissolved contaminants at the Building 100 Area began as a pilot study on March 11, 2003. Hydrogen Release Compound® (HRC) was injected through nine injection points surrounding each of three monitoring wells. Groundwater samples were collected from each of the three monitoring wells at approximately 2-month intervals through May 2004 to track the progress of HRC at remediating site contaminants. HRC was selected because it is a proven technology for optimizing degradation rates of chlorinated hydrocarbons dissolved in groundwater. The continuous hydrogen source provided by the HRC can reduce the concentration of dissolved phase chlorinated hydrocarbons by greatly enhancing the reductive dechlorination process that occurs naturally at the Building 100 Area. The *In-Situ Enhanced Bioremediation Technology to Control the Plume of Dissolved Contaminants at the Building 100 Area of the Young - Rainey STAR Center Pilot Test* final report was received from the subcontractor on April 5, 2004. The results of the pilot test indicate that the injection of HRC had a limited influence in the pilot test area. This conclusion is based on increasing concentrations of the metabolic acids (as produced from HRC) and the decreasing concentrations of sulfate and iron and the observation of ethene at one location. A supplemental sampling event was conducted in May 2004, after which the pilot test was considered complete.

Several years have passed since the Building 100 Area CMS Report (DOE 1994a), the CMIP (DOE 1996a), and the CMIP Addendum (DOE 1998) were written. Therefore, in July 2006, the Building 100 Area CMS Report Addendum was prepared to update site conditions, discuss the regulatory framework, and re-evaluate active remediation alternatives for this SWMU. Based on the recommendations included in this report, FDEP and DOE continue to discuss the closure strategy for this SWMU. One recommendation that FDEP agreed on has already been implemented, with the shutdown of the two recovery wells at Building 100 on August 21, 2006.

1.2 Northeast Site

In the late 1960s, before the construction of the East Pond, drums of waste and construction debris were disposed of in the swampy area of the Northeast Site. The East Pond was excavated in 1968 as a borrow pit. In 1986, an expansion of the East Pond was initiated to create additional storm-water retention capacity. Excavation activities ceased when contamination was detected directly west of the East Pond. EPA identified the Northeast Site as a SWMU (EPA 1992). An Interim Corrective Measures (ICM) Study was developed and submitted to EPA, and approval of this document was received in October 1991. An interim groundwater recovery system for the Northeast Site was installed, and operation commenced in January 1992.

The groundwater treatment system, as initially installed, consisted of four recovery wells equipped with pneumatic recovery pumps, a holding tank, centrifugal transfer pumps, and approximately 2,500 feet (ft) of transfer and secondary containment piping. During 1993, DOE proposed a reconfigured system for the site, consisting of four shallow and three deep recovery wells. After EPA approved the upgrade, the system was reconfigured and became operational on March 1, 1994.

Between August and October 1995, after EPA and FDEP granted their approval, a portion of the Northeast Site was excavated to remove debris and other materials that could inhibit future corrective measures. The location of the areas of excavation was based primarily on the results of a geophysical survey and knowledge of existing utility locations. Detailed descriptions of the debris-removal activities were submitted to EPA and FDEP as part of the *Northeast Site Interim Measures Quarterly Progress Report* (DOE 1996b).

In 1996, DOE submitted a CMIP to EPA Region IV and FDEP. This plan was approved by both regulatory agencies in 1997. As part of the Northeast Site CMS and CMIP, a pump-and-treat system, in conjunction with a subsurface hydrogeologic barrier wall to prevent the migration of the contaminant plume, was identified as the best available technology. A pretreatment system for iron removal, an air-stripper unit, and a tank for holding treated groundwater before discharge to the Pinellas County Publicly Owned Treatment Works were recommended. The treatment system was constructed in early 1997 and became operational by July 1997, with seven Northeast Site recovery wells and two Building 100 recovery wells pumping to the system influent tank. Subsequently several additional recovery wells were installed, and some of the old recovery wells were abandoned.

During 1997, anaerobic bioremediation and rotary steam stripping pilot tests were conducted in the northern and southern portions of the Northeast Site, respectively. These tests were designed by an Innovative Treatment Remediation Demonstration group of regulatory and industry members to provide remedial options at the STAR Center. At the conclusion of the field tests in July 1997, pump-and-treat technology resumed at the Northeast Site.

An *Interim Measures Work Plan for Remediation of Non-Aqueous Phase Liquids* (NAPLs) *at the Northeast Site* was submitted to FDEP in late November 2001. The purpose of this document was to present the plan for the ICM to remediate NAPLs at the Northeast Site. An ICM was considered to be warranted because it supported the long-term corrective action to remediate the dissolved phase contamination in the surficial aquifer to FDEP drinking water MCLs. Without this measure, NAPLs would continue to act as a source of dissolved contamination, resulting in contaminant concentrations in groundwater well above the MCLs. FDEP approved this document on January 10, 2002.

Concurrent with the preparation of the ICM Plan, a National Environmental Policy Act (NEPA) Environmental Checklist recommending a Categorical Exclusion was approved by DOE on December 19, 2001. The categorical exclusion of the Area A pilot test activity was approved based on the fact that the NAPL remediation of Area A was a small-scale, short-term cleanup action and the siting, construction, and operation of treatment facilities were temporary and pilot-scale in size. Additionally, activities of this nature were evaluated in the 1995 *Environmental Assessment* (EA) *of Corrective Action at the Northeast Site* (DOE 1995).

A NEPA Action Review was conducted for the interim measure source removal action at Area B in October of 2002. A summary of the review concluded that Area B remediation would impact an area of approximately 38,000 square ft. The footprint of the above-ground treatment system would be about 80 ft by 80 ft, and an estimated 84,000 gallons per day of groundwater would be processed over a 24-week period of operation. The proposed interim measure, although not specifically identified in the 1995 EA, was determined to be within the scope of the proposed actions. The remedial activity would occur within the same physical boundaries and address the

same contaminants identified in the EA, but in a more concentrated form. Because the EA provided for "design modifications to reflect technological advances or site-specific conditions," it was determined that the NAPL remediation of Area B was within the scope of the existing EA. However, this flexibility was not mentioned in the Finding of No Significant Impacts (FONSI) document signed in May 1995 (Glass 1995). Therefore, it was determined that the appropriate action under NEPA would require an amendment to the FONSI to include the broader scope of activities from the EA and any additional impacts from the NAPL removal action. The FONSI was amended, reviewed by the DOE-Idaho NEPA Planning Board, and approved by the DOE Grand Junction Office NEPA Compliance Officer on February 24, 2003.

Construction of the NAPL Area A treatment system began in late May 2002, and system startup occurred on September 26, 2002. NAPL treatment was completed on February 28, 2003. Three post-treatment sampling events occurred in March, May, and August 2003. Demobilization activities began in early March and were completed in September 2003. The *Northeast Site Area A NAPL Remediation Final Report* (DOE 2003b), describing thermal remediation of Area A, was sent to stakeholders on September 25, 2003.

At the end of February 2004, a contract was awarded for the remediation of NAPL Area B using the electro-thermal dynamic stripping process. Construction of the NAPL Area B treatment system began in July 2004 and was completed in early August 2005. Operations began on August 16, 2005, and were completed on June 12, 2006. Heating resumed in a focused area from July 19, 2006, until August 25, 2006, to address groundwater concentrations that exceeded remediation goals at two locations. The treatment system was permanently shut down on August 29, 2006. Approximately 18,000 pounds of contaminants were removed during operations. Confirmatory sampling activities were completed by the end of September 2006. The *Final Report Northeast Site Area B NAPL Remediation Project at the Young - Rainey STAR Center Largo, Pinellas County, Florida* (DOE 2007) describes Area B remediation.

Currently there is no ongoing remedial action at the Northeast Site. Monitoring wells have been installed at the former NAPL areas to monitor the remaining dissolved phase plumes.

1.3 WWNA/Building 200 Area

The WWNA/Building 200 Area includes the active Industrial Wastewater Neutralization Facility (IWNF), the area around Building 200, and the area south of the neutralization facility. The IWNF refers to the physical treatment facility that currently receives sanitary and industrial wastewater and has been in operation since 1957.

A CMS Report and CMIP were completed in 1997 for this SWMU because vinyl chloride (VC), trichloroethene (TCE), and arsenic were detected in surficial aquifer groundwater at concentrations above federal and state MCLs. The recommended remediation alternative for the WWNA/Building 200 Area was groundwater recovery with the Building 100 Area wells and an additional recovery well located in the WWNA. The CMIP recommended that recovered water from the additional well be discharged directly to the IWNF. This well was designed to withdraw surficial aquifer groundwater directly from the arsenic plume and thereby reduce the contaminant mass and prevent contaminant migration.

FDEP's response to the CMS/CMIP, concerning arsenic contamination in the upper 2 ft of soil, suggested that a treatment technology, air sparging, was eliminated too early. DOE then proposed a multi-phased Interim Action that included operating the recovery well for 6 months, then pulsing the system, as well as performing geochemical analyses and leaching studies of the site. On January 21, 1999, FDEP approved the proposed interim remedial action.

Additionally, EPA Region IV also approved the interim remedial action and concurred with FDEP's position regarding the arsenic contamination. EPA also requested an addendum or modification to the CMIP that would address DOE's final selection of the remediation technology and include a timeline for the completion of these activities.

In early June 1999, the WWNA recovery well commenced operation. All arsenic concentrations in water from the WWNA recovery well, PIN18−RW01, were below the STAR Center's daily maximum discharge standard for arsenic in wastewater of 0.20 milligrams per liter (mg/L) until shutdown.

Additional details concerning the impacts of groundwater extraction are reported in the WWNA/Building 200 Area CMIP Addendum (DOE 2000b). Modifications to the recovery of groundwater were proposed based on data collected through November 1999 and consisted of the installation of two new recovery wells screened at shallow intervals and the abandonment of RW01. The CMIP Addendum was submitted to the regulators and approved by FDEP and EPA in 2000. A Statement of Basis (DOE 2000a) was issued by DOE in late September 2000. This document provides a summary of environmental investigations and proposed cleanup alternatives for the WWNA/Building 200 Area. Part of DOE's proposed final action for the WWNA was to shut down the three extraction wells and begin a 1-year monitoring period. Verbal approval for this action was received from FDEP on December 20, 2005, and the wells were shut down that day. A No Further Action With Controls Proposal for the WWNA/ Building 200 Area was submitted to FDEP on March 14, 2007.

1.4 Site Update

Risk-Based Corrective Action (RBCA) rules are currently being evaluated for applicability to assist in expediting closure at some or all of the SWMUs at the STAR Center. Technical discussions regarding RBCA as the proposed final action continued between FDEP and DOE. Additionally, DOE is currently evaluating remediation alternatives for the Building 100 Area in light of the RBCA rules.

Part of the evaluation of remediation alternatives for the Building 100 Area involves the development and application of three numerical models that were used to project the spatial extent and potential future disposition of VOCs in groundwater beneath and near the Building 100 Area. This evaluation is ongoing and should be completed in early 2008.

Pinellas County is planning a major road construction effort along Bryan Dairy and Belcher Roads that will begin in late 2008. DOE is evaluating the effect, if any, that the Building 100 Area groundwater plume might have upon road construction activities along the east and south sides of the STAR Center. Seven small-diameter monitoring well pairs were installed in October along the southeast part of the STAR Center. Four well pairs were placed along Bryan Dairy Road and three well pairs were placed along Belcher Road. These well pairs consist of small-

diameter wells with one well screened from 10−20 ft and another well screened from 20 to 30 ft below land surface (bls). In December, a third small-diameter well will be added at each location and will be screened from 30 to 40 ft bls or to top of the Hawthorn, which ever comes first. Additional soil borings and groundwater monitoring wells are being installed in December 2007 and January 2008 to further assess the composition of the sediments and the quality of the groundwater in those areas.

Groundwater samples from a few wells in a recently remediated area at the Northeast Site continue to show high concentrations of NAPL compounds. Soil borings are being planned for early 2008 to delineate the area around each hot spot that may still contain NAPL at high concentrations. Once the areas have been delineated, treatment technologies will be evaluated and one chosen that will be implemented to treat the hot spot area.

1.5 Site Activities

- Water-level measurements were obtained from all accessible monitoring wells, recovery wells, and ponds on September 11, 2007.
- The semiannual sampling event was conducted in September 2007. The sampling event included collecting water samples from 105 monitoring and former recovery wells.
- The results of the semiannual sampling event were reported (this document).

2.0 Water-Level Elevations

2.1 Work Conducted and Methods

On June 8, 2007, and September 11, 2007, depth-to-water measurements were taken at all accessible monitoring wells, former extraction wells, and ponds at the STAR Center and two offsite ponds. The water levels were measured with an electronic water-level indicator or directly from a staff gauge. Groundwater elevations are listed in Table 1.

2.2 Groundwater Flow

Groundwater and surface-water elevations were used to construct sitewide groundwater contour maps of the shallow and deep surficial aquifers for the June data (Plates 1 and 2, respectively) and the September data (Plates 3 and 4, respectively). Individual contour maps were also constructed for the shallow and deep surficial aquifers at the Northeast Site and the Building 100 Area (Figure 3 through Figure 10).

Previously, water levels throughout the STAR Center indicated that the water table was highest in the general area around the West Pond. As groundwater flowed from this discharge area, it dispersed to the west, south, and east. A new pattern was observed in the shallow surficial aquifer around the West Pond and Pond 5 in September 2006, and this new pattern was observed again in both June and September 2007. As shown on Plates 1 and 2, the West Pond and Pond 5 now act as recharge points for the surficial aquifer. During recent construction activities at the site, the West Pond was cleaned out, Pond 5 was excavated, and the two ponds were connected by an underground pipe. This construction work seems to have changed the flow pattern in this

area of the site to what we observe now. The flow pattern in the deep surficial aquifer is consistent with previously observed flow patterns.

At the Northeast Site, a return to the natural flow pattern of flow generally to the east was again observed in June and September 2007 following the completion of NAPL remediation in August 2006. Along the northern boundary of the Northeast Site, the contours near the slurry wall for the past several years have indicated that the wall has been a significant barrier to groundwater flow. This pattern was observed again in June and September 2007. As shown in Figure 4 and Figure 6, in June there was a differential of 0.60 ft, and in September there was a differential of 0.57 ft, between the downgradient and upgradient sides of the wall as measured in monitoring wells PIN15−M24D and −M33D, respectively. This differential is less than the historical range of about 2 to 5 ft, but it is consistent with the differentials observed during the past 2 years. Water-table elevations indicate that the East Pond acted as a discharge point for the shallow surficial aquifer in June and September 2007 (Figure 3 and Figure 5).

In the shallow surficial aquifer at the Northeast Site, the hydraulic gradient was about 0.003 feet per foot (ft/ft), with flow toward the east (Plates 1 and 3). Calculations using Darcy's Law, along with approximations of 1 ft/day for hydraulic conductivity and 0.3 for effective porosity, indicate that groundwater at the Northeast Site is estimated to move about 3 to 4 ft/year. This velocity is less than the historical estimates of 17 to 22 ft/year but consistent with the velocities observed since March 2006. Similar flow patterns were observed in the deep surficial aquifer (Plates 2 and 4).

At the WWNA, there was a radial flow in all directions, which came from a small groundwater mound in the surficial aquifer. This flow pattern is consistent with that observed the previous 2 years.

At Building 100, the surficial aquifer is no longer influenced by groundwater withdrawals from recovery wells PIN12−RW01 and –RW02 which were shut off in August 2006. For the past 5 years, shallow groundwater beneath Building 100 has been observed to flow to the southeast under a very slight gradient. This flow pattern was observed again in June and September 2007. The hydraulic gradient at the Building 100 Area was about 0.001 ft/ft. Using the approximations mentioned above, groundwater flow velocity in this area is estimated to be less than 2 ft/year.

Water-level elevations in the three wells screened in the upper part of the Floridan aquifer are presented in Table 2. The water levels in these wells indicate that the potentiometric surface of the Floridan aquifer at the site was at least 0.5 ft lower in June 2007 than in September 2007.

Surface-water elevations were recorded from the East, South, Southwest, and West Ponds, Pond 5, the pond immediately north of the 4.5 Acre Site, and the pond just east of Belcher Road, and they are presented in Table 3. All the ponds are hydraulically connected to the shallow surficial aquifer system (Plates 1 and 3).

3.0 Groundwater Sampling and Analytical Results

3.1 Work Performed

During annual sampling in March 2007, groundwater samples were collected from 119 monitoring and former recovery wells. VOCs analyses were performed on 77 samples using EPA method SW-846 8260B. Arsenic was analyzed in 13 samples, and aluminum, iron, and manganese were analyzed in 54 samples using EPA method SW-846 6010B. Laboratory reports are provided in Appendix A.

Four samples were also collected for dissolved gases and microbial analyses (Table 4). The dissolved gases are ethene, ethane, and methane. The microbiological analysis is for *Dehalococcoides ethenogenes.*

All samples were collected in accordance with the Stoller *Sampling Procedures for the Young - Rainey STAR Center and 4.5 Acre Site* (DOE 2006a), using FDEP procedures. All samples were submitted to TestAmerica, Tampa, Florida, for analysis. TestAmerica, Tampa, Florida, is accredited by the Florida Department of Health in accordance with the National Environmental Laboratory Accreditation Conference (certification number E84282). All monitoring wells were micropurged using a dedicated bladder pump, and sampling was performed when the field measurements stabilized. Table 5 lists field measurements of pH, specific conductance, dissolved oxygen, oxidation-reduction potential, turbidity, and temperature recorded at the time the samples were collected. Measurements were made with a flow cell and a multiparameter instrument.

3.2 Analytical Results

3.2.1 Northeast Site (PIN15)

Concentrations of contaminants of potential concern (COPCs) in samples collected from wells at the Northeast Site (PIN15) are presented in Table 6, which, for comparison purposes, also shows the previous year of data. Figure 11 shows the total COPCs (TCOPCs) concentrations. The highest TCOPCs concentration− 11,900 micrograms per liter (µg/L)—was measured in well PIN15−0587. Table 7 shows the results of arsenic sampling at four Northeast Site wells. Arsenic concentrations ranged from 0.018 to 0.075 mg/L, with the highest value detected in well PIN15−M03S.

As described in the Annual Monitoring Plan (DOE 2006b), special sampling was conducted at the Northeast Site during this sampling event to determine the aluminum, iron, and manganese concentrations remaining following NAPL remediation. All Northeast Site monitoring wells were sampled and analyzed for aluminum, iron, and manganese using EPA Method 6010B. The results demonstrated that iron and aluminum concentrations exceeded Cleanup Target Levels (CTL) at several locations and manganese concentrations did not exceed the CTL (Table 8).

3.2.2 Building 100 Area (PIN06, PIN09, PIN10, PIN12, and PIN21)

TCOPCs concentrations in samples collected from wells at the Building 100 Area are included in Table 9, which, for comparison purposes, also shows the previous year of data. Figure 12 shows

the TCOPCs concentrations, the highest of which was measured in well S35B at 34,190 µg/L. Table 7 shows the results of arsenic sampling in the Building 100 Area. The highest arsenic concentration, 0.060 mg/L, was measured in well S68B.

3.3 Quality Assurance/Quality Control

The results from the analytical laboratory, Severn-Trent Laboratories, were checked for quality assurance/quality control (QA/QC) through duplicate samples and trip blanks. Detected analytes for each duplicate sample collected from the STAR Center are listed in Table 10. The duplicate sample results were compared and the relative percent differences (RPDs) between the results were calculated. Sample PIN12−0524 had an RPD value of 57 percent for 1,1-dichloroethene (DCE) and sample PIN15−0568 had an RPD value of 63 percent for aluminum. All other data passed QA/QC criteria at a Class A level, indicating that the data may be used for quantitative and qualitative purposes.

As specified in the *Sampling Procedures for the Young - Rainey STAR Center and 4.5 Acre Site* (DOE 2006a), duplicate samples should be collected at a frequency of one duplicate for every 20 or fewer samples. For the STAR Center and the 4.5 Acre Site, there were 160 groundwater samples collected, with 8 duplicate samples collected. The duplicate requirements for this sampling event were nearly met. There were 10 trip blanks collected during this event.

A data validation software module for identifying and tracking anomalous groundwater data points within the SEEPro database was used to generate a report of analytical results that fall outside of historical minimum or maximum values. The manganese result for location PIN15−M03S was identified as a potential outlier. There is no evidence of laboratory errors and the data for this report identification number are acceptable as qualified. No other anomalous data were identified for this sampling event.

4.0 Data Interpretation

The purpose of this data-interpretation section is to aid in the evaluation of plume stability. Time-versus-concentration plots were generated to aid in the interpretation.

While most of the previous documents for the Pinellas site have compared groundwater contaminant concentrations to drinking water standards (i.e., MCLs), those standards are not the applicable default CTLs for the purpose of evaluating site remediation under RBCA. Based on a comprehensive review of background data for the site (DOE 2003a), it has been determined that aluminum and iron levels in the shallow groundwater in the site vicinity are naturally elevated and far exceed State of Florida Secondary Drinking Water Standards (Chapter 62-550, Florida Administrative Code [F.A.C.]). Specifically, the average background concentration of 1.1 mg/L for aluminum exceeds the 0.2 mg/L secondary standard, and the average background concentration for iron (9.3 mg/L) exceeds the 0.3 mg/L secondary standard. The ambient shallow groundwater in the area is therefore designated as “poor quality” as defined in 62-780.200 (35), F.A.C. Thus, the applicable groundwater CTLs are those for groundwater of “low yield/poor quality” provided in Table 1 of Chapter 62-777, F.A.C. In essence, these CTL values are a factor of 10 higher than the MCL values.

4.1 Contaminant Concentration Trends

Monitoring well PIN15–0569 was chosen to evaluate plume stability at the Northeast Site. Well PIN15−0569 is located near the leading edge of the contaminant plume at the Northeast Site (Figure 11). The VC concentration in this well shows an overall decreasing concentration trend (Figure 13), indicating a stable or shrinking contaminant plume in the vicinity of this well.

Monitoring wells PIN21–0512 and PIN12–S73C were chosen to evaluate plume stability at the Building 100 Area because they are the monitoring wells nearest the property boundaries. Well 0512 lies along the southern boundary of the STAR Center and well S73C lies along the eastern boundary (Figure 12). Figure 14 illustrates the VC concentration over time in well 0512, and Figure 15 shows the VC concentration in well S73C. Well 0512 shows a relatively consistent VC concentration trend (considering the inherent sampling and analytical variability of low concentrations), with concentrations ranging between 0.3 and 14 µg/L since November 1998. Well S73C shows a decreasing VC concentration trend from 2002 to late 2003, followed by a stable trend since that time. These stable and decreasing concentration trends indicate a stable or shrinking contaminant plume near the property boundaries.

In October 2007, 14 new monitoring wells were installed along the south and east property boundaries in the Building 100 Area. The purpose of these wells was to further define the extent of the contaminant plume at the property boundary in preparation for road construction work by Pinellas County. VC was the only contaminant found above the CTL in these wells, and the revised VC plume is shown in Figure 16.

Figure 17 shows the TCE, cis-1,2-DCE, trans-1,2-DCE, and VC concentrations in well PIN12−0524, located near the southeast corner of Building 100. The concentration trends in this well suggest that a localized slug of TCE, DCE, and VC is moving through the aquifer. The concentration trends in well 0524, particularly the significant TCE decrease, indicate that the slug is nearly past the well.

4.2 Geochemical Parameters

Geochemical parameters measured in the field in all wells at the STAR Center during September 2007 are summarized in Table 5. Generally, conditions across the STAR Center are reducing as evidenced by the low values of dissolved oxygen and oxygen reduction potential.

5.0 Tasks to be Performed Semiannually

The following tasks are expected to be conducted during the next semiannual period (December 2007 through May 2008):

- The collection of soil samples from 11 soil borings along the southern edge of the STAR Center adjacent to Bryan Dairy Road.
- The installation of 18 small-diameter monitoring wells at six locations (triplets with screens from 10−20 ft, 20−30 ft, and 30−40 ft bgs off the STAR Center property. Three

locations each will be located on the opposite side from the STAR Center along Bryan Dairy and Belcher roads, respectively.

- The collection of soil samples from up to 45 soil borings around three hot-spot areas at the Northeast Site.
- The semiannual sampling and analysis of groundwater in March 2008.
- The collection of water level measurements in March 2008.
- The continuing utilization of dedicated bladder pumps for semiannual sampling using the micropurging technique.

[a]Before December 18, 2003 "<" values are reporting limits. On or after December 18, 2003 "<" values are method detection limits.
[b]Total 1,2–DCE is the sum of cis–1,2–DCE and trans–1,2–DCE
[c]Total COPC is the sum of the individual COPC concentrations. The cis–1,2–DCE value is not part of the total COPC value because this value is included in the total 1,2–DCE value. "J" values are not included in the total COPC value.
ND = Not detected.
J = Estimated value, result is between the reporting limit and the method detection limit.
Arsenic, while a COPC, is not included in this table, nor in the total COPC value.

Table 7. Sitewide Arsenic Measurements

[a]"<" values are reporting limits.
[b]Total 1,2-DCE is the sum of cis-1,2-DCE and trans-1,2-DCE.
[c]Total COPC is the sum of the individual COPC concentrations. The cis-1,2-DCE and trans-1,2-DCE values are not part of the total COPC value because these values are included in the total 1,2-DCE value. "J" values are not included in the total COPC value.

ND = Not detected.
J = Estimated value, result is between the reporting limit and the method detection limit.
Arsenic, while a COPC, is not included in this table, nor in the Total COPC value.

Table 10. Relative Percent Difference (RPD) for Duplicate Samples

Sample ID	Analyte	S	D	RPD	MDL	5xMDL	Fail?
PIN12–0524	1,1-Dichlorethylene	29	52	57	9	45	Yes
PIN12–0524	cis-1,2-Dichloroethylene	770	770	0	13	65

PIN15–0586	cis-1,2-Dichloroethylene	1,400	1,300	7	13	65	
PIN15–0586	Iron	16	18	12	0.022	0.11	
PIN15–0586	Manganese	0.049	0.052	6	0.0014	0.007	
PIN15–0586	Toluene	28	31	10	2.6	13	
PIN15–0586	Trichloroethylene	430	450	5	2.5	12.5	
PIN15–0586	Vinyl chloride	490	500	2	2.5	12.5	

S = Original sample (N001), VOC concentrations in μg/L and metals in mg/L.
D = Duplicate sample (N002), VOC concentrations in μg/L and metals in mg/L.
RL = Reporting limit.
Fail = Volatiles "fail" when the RPD is greater than ± 30% and the concentration is more than 5 times the reporting limit. Metals "fail" when the samples are more than 5 times the reporting limit and the RPD is greater than 20%. For metals samples that are less than 5 times the reporting limit the difference must be less than ± the reporting limit (this includes the case when only one of the duplicate/sample values is less than 5 times the reporting limit).
